Outline

- 1 Introduction
- 2 Hamming distance
- 3 Chebyshev distance
- 4 Kendall's τ -distance
- 5 Some new metrics

Permutation code

Definition

Let S_n be the set of all permutations of length n . The *permutation code* C is just a subset of S_n equipped with a distance metric.

The *length* of C is n and each permutation in C is called a *codeword*.

Application: Powerline communication and Flash memories

Hamming and Chebyshev metrics

Definition

For two distinct permutations $\sigma, \pi \in S_n$, their *Hamming distance* $d_H(\sigma, \pi)$ is the number of elements that they differ.

Definition

Let $\pi = \pi_1\pi_2 \dots, \pi_n, \sigma = \sigma_1\sigma_2 \dots, \sigma_n \in S_n$. The *Chebyshev distance* between π and σ is

$$d_C(\pi, \sigma) = \max\{|\pi_j - \sigma_j| \mid 1 \leq j \leq n\}.$$

Permutation code of minimum distance d

Example

Let $\sigma = 23451$ and $\pi = 12543$. Then

$$d_H(\sigma, \pi) = 5 \quad \text{and} \quad d_C(\sigma, \pi) = 2.$$

We say a permutation code C is a Hamming (n, d) -permutation code if the Hamming distance of any pair of distinct permutations in C is at least d .

Similarly, C is called a Chebyshev (n, d) -permutation code if the Chebyshev distance of any pair of distinct permutations in C is at least d .

$A_H(n, d)$ and $A_C(n, d)$

The maximum number of codewords in a Hamming (n, d) -permutation code is denoted by $A_H(n, d)$.

The maximum number of codewords in a Chebyshev (n, d) -permutation code is denoted by $A_C(n, d)$.

Problems:

- Construct permutation codes with large size under Hamming or Chebyshev distance.
- Find $A_H(n, d)$ and $A_C(n, d)$, or give some good lower or upper bounds of them.

Basic results on $A_H(n, d)$

- 1 $A_H(n, 2) = n!$;
- 2 $A_H(n, 3) = n!/2$;
- 3 $A_H(n, n) = n$;
- 4 $A_H(n, d) \leq nA_H(n - 1, d)$.

Sphere-packing bound

Definition

Let $D(n, k)$ ($k = 0, 1, \dots, n$) denote the set of all permutations in S_n which are exactly at distance k from the identity.

Clearly, $|D(n, k)| = D_k \binom{n}{k}$.

Let $B_H(n, d)$ be the size of the set of the permutations at distance at most d from the identity. Then $B_H(n, d) = \sum_{k=0}^d D_k \binom{n}{k}$.

Theorem

$$B_H(n, d) \leq \frac{n!}{\sum_{k=0}^{\lfloor \frac{d-1}{2} \rfloor} D_k \binom{n}{k}}.$$

The upper bound for $A_H(n, 4)$

Theorem (Frankl and Deza, 1977)

$$A_H(n, 4) \leq (n - 1)!.$$

Theorem (Dukes and Sawchuck, 2010)

If $k^2 \leq n \leq k^2 + k - 2$ for some integer $k \geq 2$, then

$$\frac{n!}{A_H(n, 4)} \geq 1 + \frac{(n + 1)n(n - 1)}{n(n - 1) - (n - k^2)((k + 1)^2 - n)((k + 2)(k - 1) - n)}.$$

Gilbert-Varshamov bound

Theorem

$$A_H(n, d) \geq \frac{n!}{\sum_{k=0}^{d-1} D_k \binom{n}{k}}.$$

Graph theory model

We define a *Cayley graph*

$$\Gamma(n, d) := \Gamma(S_n, S(n, d - 1)),$$

where $S(n, d - 1)$ is the set of all the permutations with more than $n - d$ fixed points.

By the definition, $\Gamma(n, d)$ is a regular graph of degree which equals the size of the generating set, i.e.,

$$\Delta(n, d) = |S(n, d - 1)| = \sum_{k=1}^{d-1} \binom{n}{k} D_k.$$

The codewords of an (n, d) permutation code are vertices of an independent set in $\Gamma(n, d)$. Conversely, any independent set in $\Gamma(n, d)$ is an (n, d) -permutation code.

A result on the independent number

For $m \geq 1$ and $x \geq 0$, we define the function $f_m(x)$ by

$$f_m(x) = \int_0^1 \frac{(1-t)^{1/m}}{m + (x-m)t} dt.$$

Theorem (Li and Rousseau, 1996)

Let $m \geq 1$ be an integer, and let G be a graph of order N with average degree Δ . If any subgraph induced by a neighborhood has maximum degree less than m , then

$$\alpha(G) \geq N \cdot f_m(\Delta) \geq N \cdot \frac{\log(\Delta/m) - 1}{\Delta}.$$

Our improvement for small d I

We use $G(n, d)$ to denote the subgraph induced by the neighborhood of identity in $\Gamma(n, d)$. Then $G(n, d)$ has vertex set

$$V(G(n, d)) = S(n, d - 1) = \bigcup_{k=1}^{d-1} D(n, k).$$

We denote the maximum degree in $G(n, d)$ by $m(n, d)$.

Lemma

For any positive integer $n \geq 7$, we have $m(n, 2) = 0$, $m(n, 3) = 0$, $m(n, 4) = 4n - 8$, $m(n, 5) = 7n^2 - 31n + 34$.

Our improvement for small d II

Theorem (Gao, Yang and Ge, 2013)

Let $m'(n, d) = m(n, d) + 1$, and

$$A_H^{IS}(n, d) := n! \cdot \int_0^1 \frac{(1-t)^{1/m'(n,d)}}{m'(n,d) + [\Delta(n,d) - m'(n,d)]t} \cdot dt.$$

Then $A_H(n, d) \geq A_H^{IS}(n, d)$.

$A_H^{IS}(13, 5) = 2147724$ greatly improves the best known result which is $A_H(13, 5) \geq 878778$.

Asymptotic results

Lemma

When n goes to infinity,

$$m(n, d) = O(n^{d-3}).$$

Theorem (Gao, Yang and Ge, 2013)

When d is fixed and n goes to infinity, we have

$$\frac{A_H^{IS}(n, d)}{A_H^{GV}(n, d)} = \Omega(\log(n)).$$

The case d/n is fixed

Theorem (Tait, Vardy, and Verstraete, 2015)

Let d/n be a fixed ratio with $0 < d/n < 1/2$. Then as $n \rightarrow \infty$, then

$$A_H(n, d) = \Omega \left(\log n \frac{n!}{B_H(d-1)} \right).$$

Our further improvement

Theorem (Wang, Yang, Zhang and Ge, 2017)

Let n, d be integers and let p be a prime greater than or equal to n . Then, we have

$$A_H(n, d) \geq \frac{n!}{p^{d-2}}.$$

Corollary

Let d be fixed and $n \rightarrow \infty$. Then

$$A_H(n, d) = \Omega \left(n \frac{n!}{B_H(d-1)} \right).$$

Idea of the proof

Idea: For any graph G of order n , $\alpha(G) \geq \frac{n}{\chi(G)}$.

Consider the coloring $f : S_n \rightarrow \mathbb{Z}_p^{d-1}$ whose value at $\sigma \in S_n$ is defined by

$$f(\sigma) = A\sigma \pmod{p},$$

where A is a $(d-1) \times n$ Vandermonde matrix as follows (a_1, a_2, \dots, a_n are distinct numbers in $\{0, 1, \dots, p-1\}$):

$$\begin{pmatrix} 1 & 1 & \dots & 1 \\ a_1 & a_2 & \dots & a_n \\ \vdots & \vdots & \ddots & \vdots \\ a_1^{d-2} & a_2^{d-2} & \dots & a_n^{d-2} \end{pmatrix}$$

Claim: This coloring is a proper coloring with p^{d-2} colors.

Sphere-packing and GV bounds on $A_C(n, d)$

Let $B_C(n, d)$ denote the number of permutations in S_n within Chebyshev distance d from the identity permutation.

Theorem

$$\frac{n!}{B_C(n, d-1)} \leq A_C(n, d) \leq \frac{n!}{B_C(n, \lfloor (d-1)/2 \rfloor)}.$$

Permanent and $B_C(n, d)$

Definition

Let A be a $n \times n$ matrix. Then the permanent of A is defined by

$$\text{per} A = \sum_{\pi \in S_n} a_{1, \pi_1} \cdots a_{n, \pi_n}.$$

Let $A^{(n,d)}$ be the $n \times n$ matrix with $a_{i,j}^{(n,d)} = 1$ if $|i - j| \leq d$ and $a_{i,j}^{(n,d)} = 0$ otherwise.

Lemma

$$B_C(n, d) = \text{per} A^{(n,d)}.$$

Upper bound for $B_C(n, d)$

Lemma

$$\text{per} A \leq \prod_{i=1}^n (r_i!)^{1/r_i},$$

where r_i is the number of ones in row i .

Theorem (Kløve et al., 2010)

$$B_C(n, d) \leq [(2d + 1)!]^{n/(2d+1)}.$$

Construction of $B^{(n,d)}$

Define the matrix $B^{(n,d)}$ as follows:

$$b_{i,j}^{(n,d)} = \begin{cases} 0 & \text{if } i > j + d \text{ or } j > i + d, \\ 2 & \text{if } i + j \leq d + 1 \text{ or } i + j \geq 2n + 1 - d, \\ 1 & \text{otherwise.} \end{cases}$$

Theorem (Kløve, 2011)

$$\text{per} B^{(n,d)} \leq 2^{2d} \text{per} A^{(n,d)}.$$

Example

$$A^{(6,2)} = \begin{pmatrix} 1 & 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 & 0 & 0 \\ 1 & 1 & 1 & 1 & 1 & 0 \\ 0 & 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 & 1 \end{pmatrix}$$

$$B^{(6,2)} = \begin{pmatrix} 2 & 2 & 1 & 0 & 0 & 0 \\ 2 & 1 & 1 & 1 & 0 & 0 \\ 1 & 1 & 1 & 1 & 1 & 0 \\ 0 & 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 & 1 & 2 \\ 0 & 0 & 0 & 1 & 2 & 2 \end{pmatrix}$$

Lower bound for $B_C(n, d)$

Theorem

If A is an $n \times n$ matrix where the sum of the elements in any row or column is k , then

$$\text{per } A \geq n!k^n/n^n.$$

Theorem (Kløve, 2011)

$$B_C(n, d) \geq \frac{n!(2d+1)^n}{2^{2d}n^n}.$$

Bounds for $A_C(n, d)$

Theorem (Kløve, 2010)

$$\frac{n!}{[(2d-1)!]^{n/(2d-1)}} \leq A_C(n, d) \leq \frac{2^{d-1}n^n}{d^n}.$$

A better lower bound for $B_C(n, d)$

Let $B_{d,2}$ be the upper left corner of $B^{(n,d)}$.

Theorem (Kløve, 2011)

$$\text{per}B^{(n+2d,d)} \leq \text{per}A^{(n,d)} \text{per}(B_{d,2})^2.$$

Conjecture (Kløve, 2011)

For any positive integer d ,

$$\text{per}(B_{d,2}) = \sum_{m=0}^d \binom{d}{m} (m+1)^d.$$

Proof of Kløve's conjecture

Theorem (Guo and Yang, 2017)

$$\text{per}(B_{d,x}) = \sum_{m=0}^d \binom{d}{m} (m+1)^d (x-1)^{d-m}.$$

It is equivalent to

$$\text{per}(B_{d,x+1}) = \sum_{m=0}^d \binom{d}{m} (d-m+1)^d x^m. \quad (4.1)$$

Therefore, it suffices to show that the coefficient b_m of x^m in $\text{per}(B_{d,x+1})$ is equal to $\binom{d}{m} (d-m+1)^d$.

What does the matrix $B_{d,x+1}$ look like?

$$B_{2,x+1} = \begin{pmatrix} x+1 & x+1 & 1 & 0 \\ x+1 & 1 & 1 & 1 \end{pmatrix},$$

$$B_{3,x+1} = \begin{pmatrix} x+1 & x+1 & x+1 & 1 & 0 & 0 \\ x+1 & x+1 & 1 & 1 & 1 & 0 \\ x+1 & 1 & 1 & 1 & 1 & 1 \end{pmatrix}.$$

Kendall's τ -metric

Definition

Given a permutation $\sigma \in S_n$, an adjacent transposition, $(i, i + 1)$, for some $1 \leq i \leq n - 1$, is an exchange of the two adjacent elements $\sigma(i)$ and $\sigma(i + 1)$ in σ .

Definition

Given two permutations $\sigma, \pi \in S_n$, the Kendall's τ -distance between σ and π , $d_K(\sigma, \pi)$, is defined as the minimum number of adjacent transpositions needed to transform σ into π .

Basic properties

Theorem (Barg and Mazumdar, 2010)

For $\sigma, \pi \in S_n$,

$$d_K(\sigma, \pi) = |\{(i, j) : \sigma^{-1}(i) < \sigma^{-1}(j) \wedge \pi^{-1}(i) > \pi^{-1}(j)\}|.$$

Corollary

For $\sigma, \pi \in S_n$,

$$d_K(\sigma, \pi) + d_K(\sigma^r, \pi) = \binom{n}{2}.$$

Bounds on $A_K(n, d)$

Definition

A permutation code C under Kendall's τ -metric with minimum distance d is a subset of S_n such that any two distinct permutations σ and π , $d_K(\sigma, \pi) \geq d$.

Let $A_K(n, d)$ be the size of the code with the maximum size.

Theorem (Jiang, Schwartz and Bruck, 2010)

$$\frac{n!}{B_K(d-1)} \leq A_K(n, d) \leq \frac{n!}{B_K(\lfloor \frac{d-1}{2} \rfloor)}.$$

Our improvement for the lower bound

Theorem (Barg and Mazumdar, 2010)

Let $m = ((n - 2)^{t+1} - 3)/(n - 3)$, where $n - 2$ is a prime power.
Then we have

$$A_K(n, 2t + 1) \geq \begin{cases} n!/(t(t + 1)m), & t \text{ odd;} \\ n!/(t(t + 2)m), & t \text{ even.} \end{cases}$$

Theorem (Wang, Yang, Zhang and Ge, 2017)

Let $m = ((n - 2)^{t+1} - 3)/(n - 3)$, where $n - 2$ is a prime power.
Then we have

$$A_K(n, 2t + 1) \geq \frac{n!}{(2t + 1)m}.$$

Upper bounds

Definition

An anticode \mathcal{A} of diameter D in S_n is a subset \mathcal{A} of S_n such that $d_K(x, y) \leq D$ for any $x, y \in \mathcal{A}$.

Theorem (Buzaglo and Etzion, 2015)

If a code $\mathcal{C} \subset S_n$ has minimum Kendall's τ -distance d , and an anticode $\mathcal{A} \subset S_n$ has maximum Kendall's τ -distance $d - 1$, then

$$|\mathcal{C}| \leq \frac{n!}{|\mathcal{A}|}.$$

Two open problems on the anticodes

Definition

Let $x, y \in S_n$ such that $d_K(x, y) = 1$, the double ball of radius R centered at x and y is defined by

$$DB(x, y, R) = B(x, R) \cup B(y, R).$$

1. Is a ball with radius R in S_n always optimal as an anticode with diameter $2R$ in S_n , for $2 \leq R \leq \frac{\binom{n}{2}}{2}$?
2. Is the double ball with radius R in S_n always optimal as an anticode with diameter $2R + 1$ in S_n , for $2 \leq R \leq \frac{\binom{n}{2} - 1}{2}$?

Some other metrics

- Ulam metric d_U : minimum number of translocations needed.
- Calay metric d_C : minimum number of transpositions needed.
- Generalized Cayley metric d_{gC} : minimum number of interval transpositions needed.
- Generalized Kendall τ -metric d_{gK} : minimum number of interval adjacent transpositions needed.

Clearly, we have the following inequality:

$$d_{gC}(\pi_1, \pi_2) \leq d_{gK}(\pi_1, \pi_2) \leq d_U(\pi_1, \pi_2) \leq d_K(\pi_1, \pi_2).$$

Block permutation distance

Definition

The block permutation distance between π_1 and π_2 ($d_B(\pi_1, \pi_2)$) is d if and only if $(d + 1)$ is the minimum number of blocks the permutation π_1 needs to be divided into in order to obtain π_2 through block level permutation.

Theorem (S.Yang et al.,2019)

$$d_{gC}(\pi_1, \pi_2) \leq d_B(\pi_1, \pi_2) \leq 4d_{gC}(\pi_1, \pi_2).$$
